2014 PSMFC Steelhead Management Meeting

3/19/2014

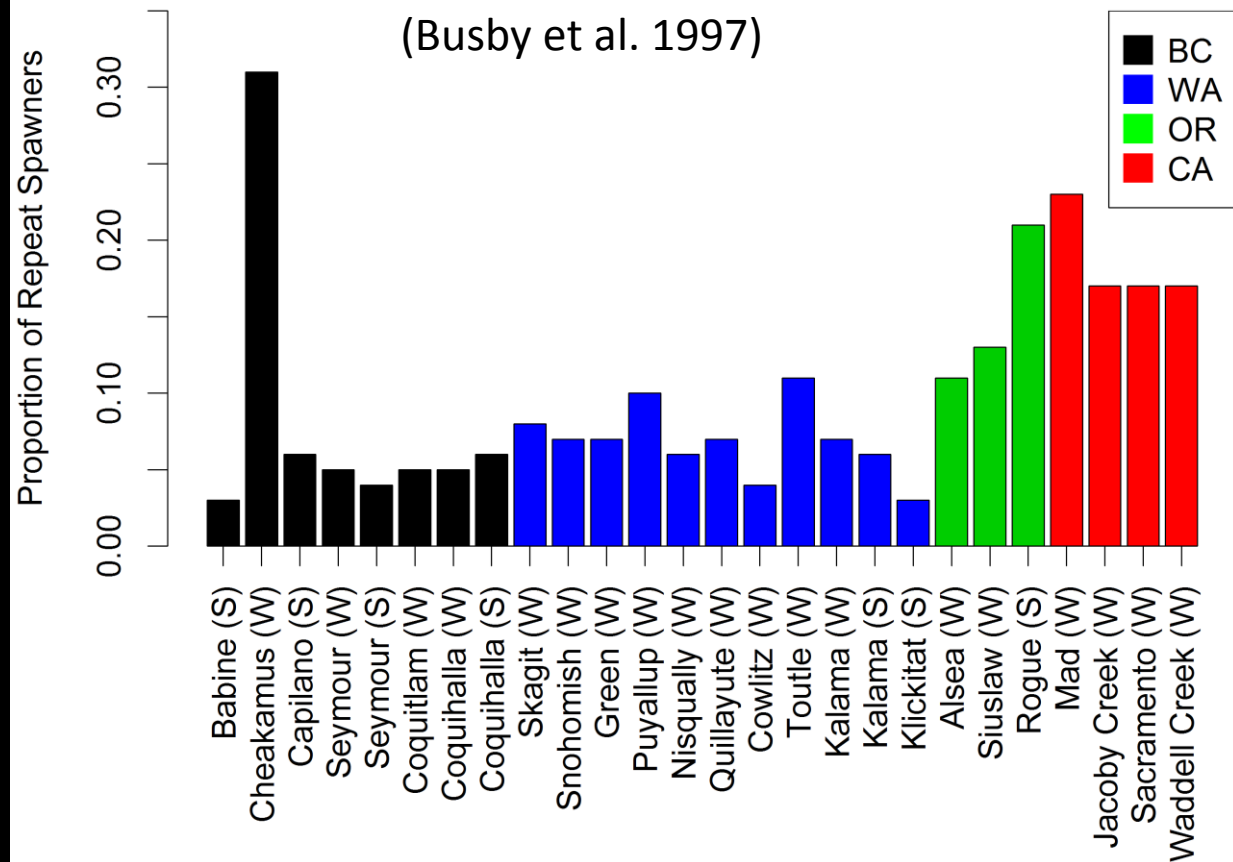

Talk Outline

- Background on steelhead iteroparity
- Wind River data collection methods
- Rates of iteroparity
- Factors influencing iteroparity
- Implications of iteroparity

Background on Iteroparity

- Variable across range
- Maybe higher N & S
- Generally 5-20%
- Benefits:
 - Multiple spawning events
 - Larger size

Background on Iteroparity

- Repeat Spawner Rates VERY low in Columbia River Hydrosystem

Talk Outline

- Background on steelhead iteroparity
- Wind River data collection methods

Basin:

Drainage area: 580 km²
 Elevations from 30-1200 m
 Rain dominated hydrograph
 Monthly Mean Discharge 5.7-60 cms

Land Ownership & Use:

77% USFS multi-purpose
 23% timber, rural residential

Location:

Columbia River rkm 250
 10 km > Bonneville Dam

Anadromous fish:

Summer Steelhead
 (Hatchery Spring Chinook)

Shiphord Falls (rkm 3)

Barrier to salmon
 Wild steelhead refuge (pHOS 1%)

Adult Monitoring

- Abundance
 - Floy tag adults at Shipherd Falls fish ladder
 - Snorkel to count tagged and untagged adults (2000-pres.)
- Bio-Samples
 - Scales, length, sex, origin
 - Tags
 - Floy – since 2000
 - PIT – since 2007

Juvenile Monitoring

- 4 smolt traps
 - All start between 1992- and 1998
 - Smolt abundance
 - Parr abundance (index)
 - Bio-Samples
 - Lengths
 - Scales
 - PIT tags
 - partial since 2003
 - all smolts since 2005

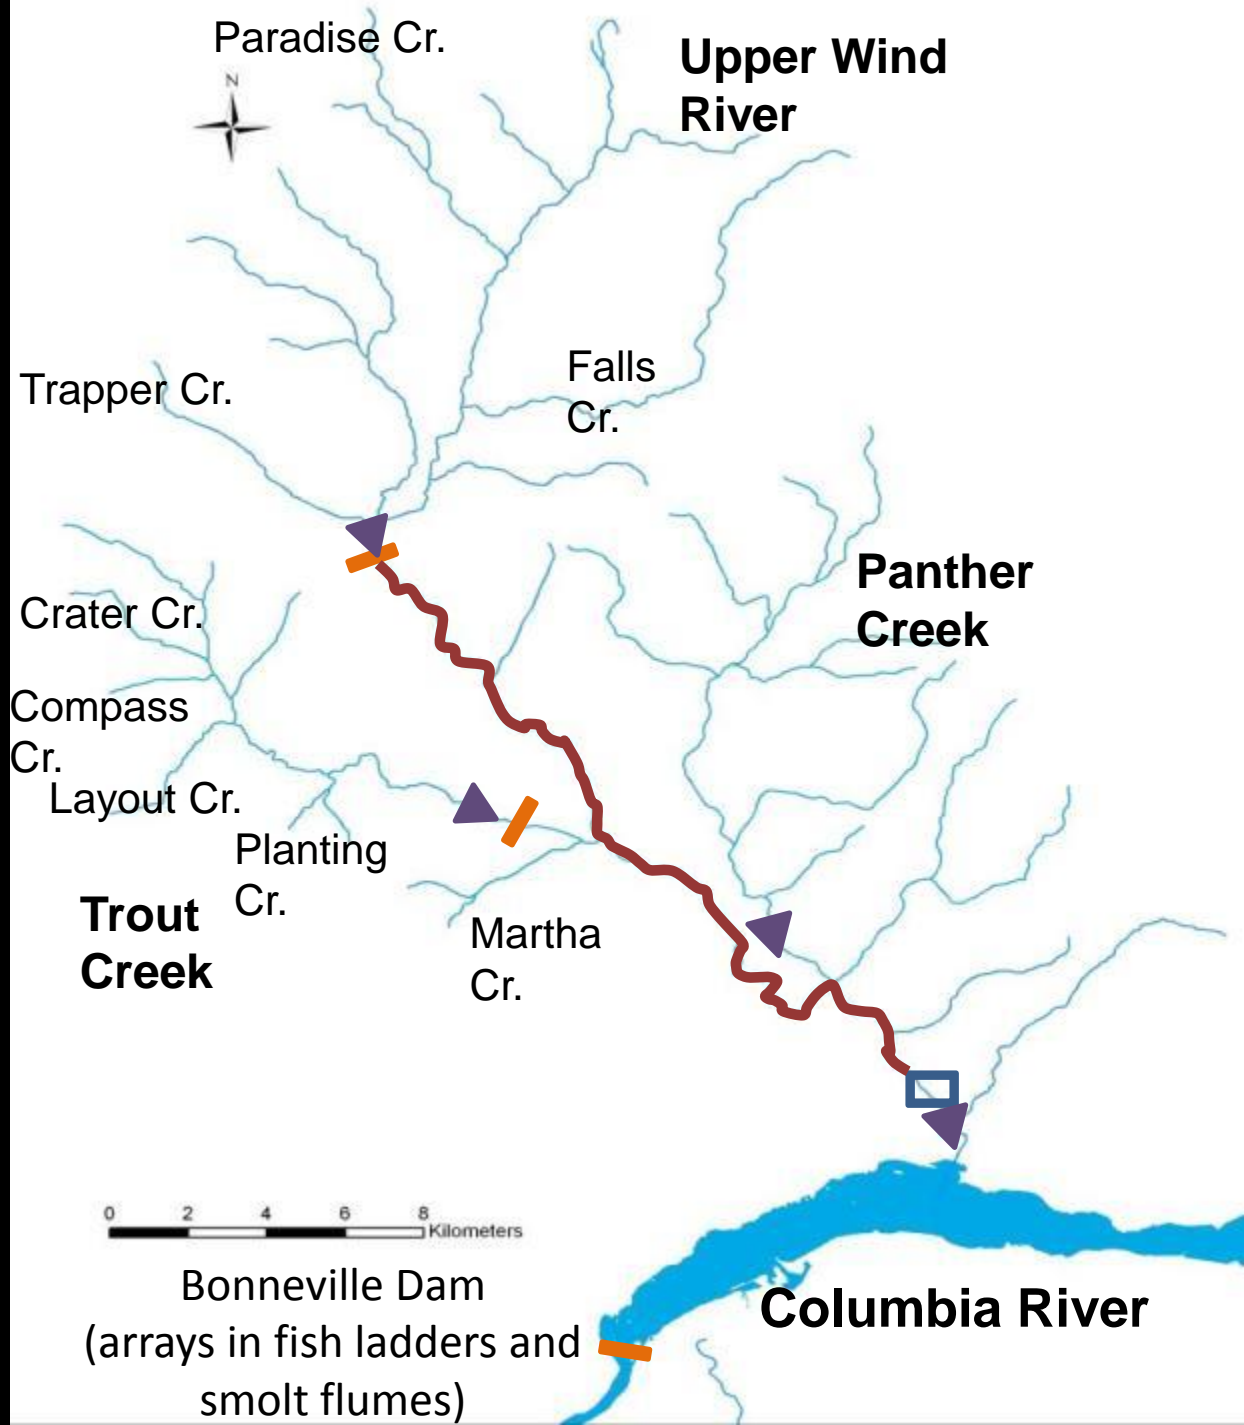

Data Sites

— PIT Tag Array (MUX)

▣ Shipherd Falls Adult trap

~ Snorkel re-sight reach

▼ Smolt trap

PIT Tag Detection Locations for Repeat Spawners

Columbia River

Wind River Watershed

Bonneville Dam
Ladder and
Smolt /Kelt PIT
Arrays

Shipherd
Falls Trap

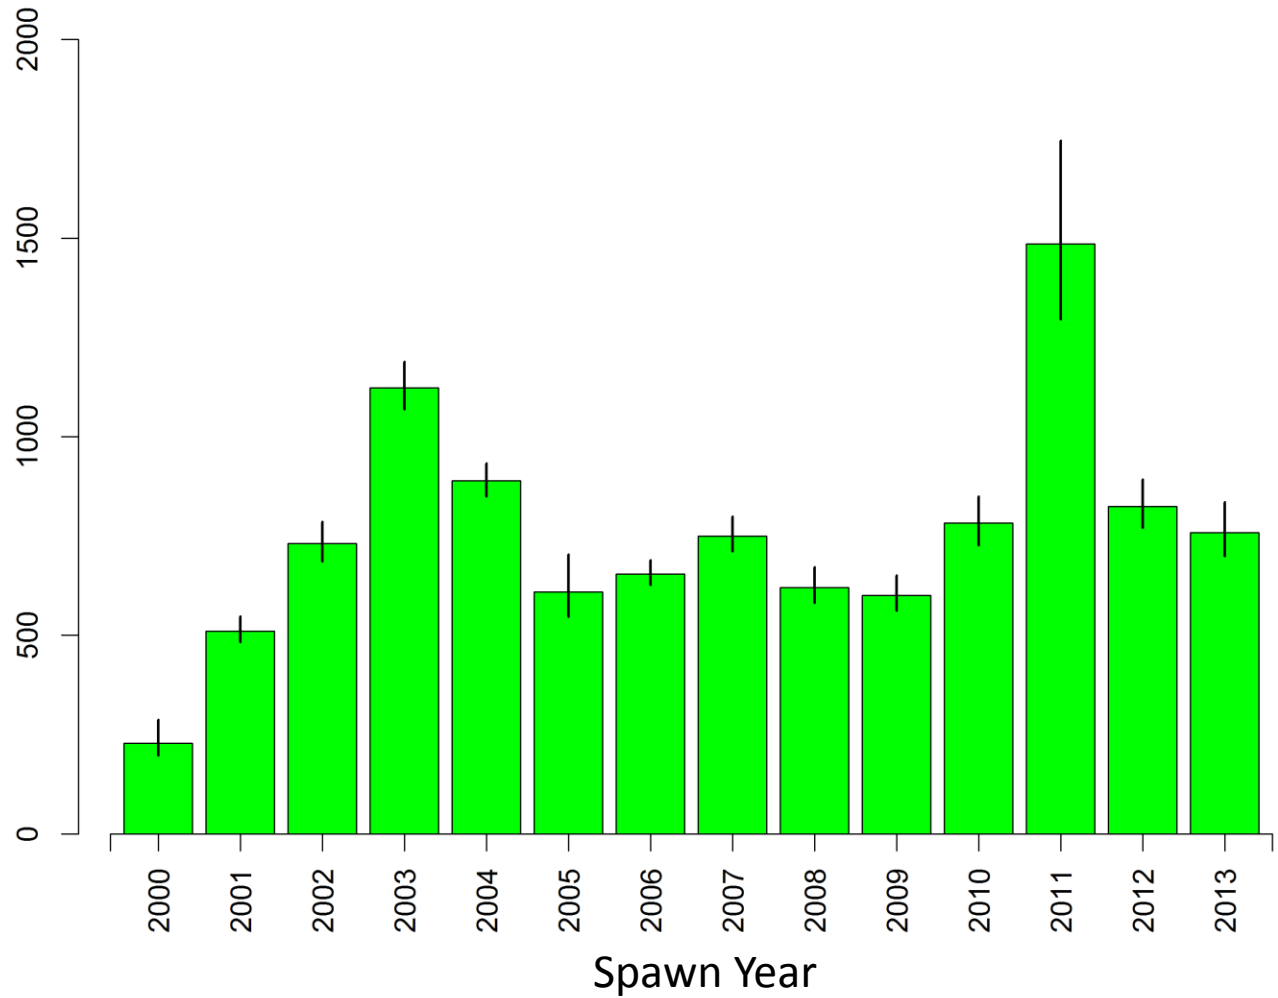

Wind River Steelhead

Dominated by
summer runs;
May-October
passage at BON

Wind River Steelhead

Abundance ranges from 200-1500 adults by spawn year

Wind River Steelhead

Ocean Age of Maiden
Spawners dominated by
2-salts

Maiden Steelhead Ocean Age

■ 1 ■ 2 ■ 3

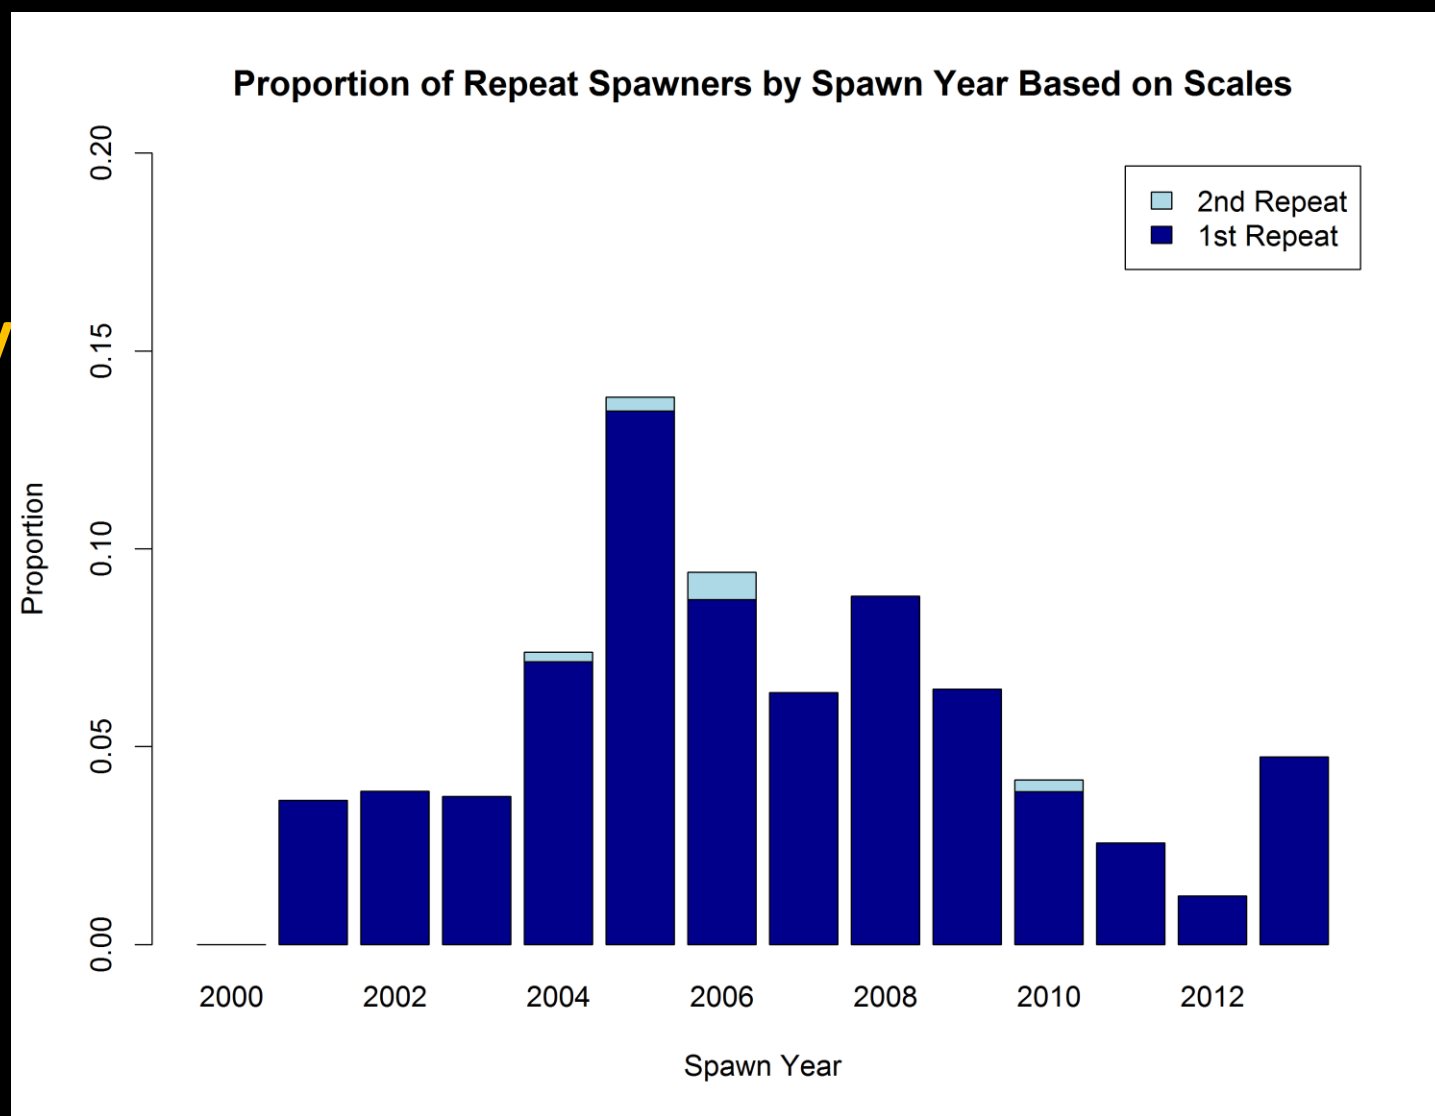

Talk Outline

- Background on steelhead iteroparity
- Wind River data collection methods
- Rates of iteroparity

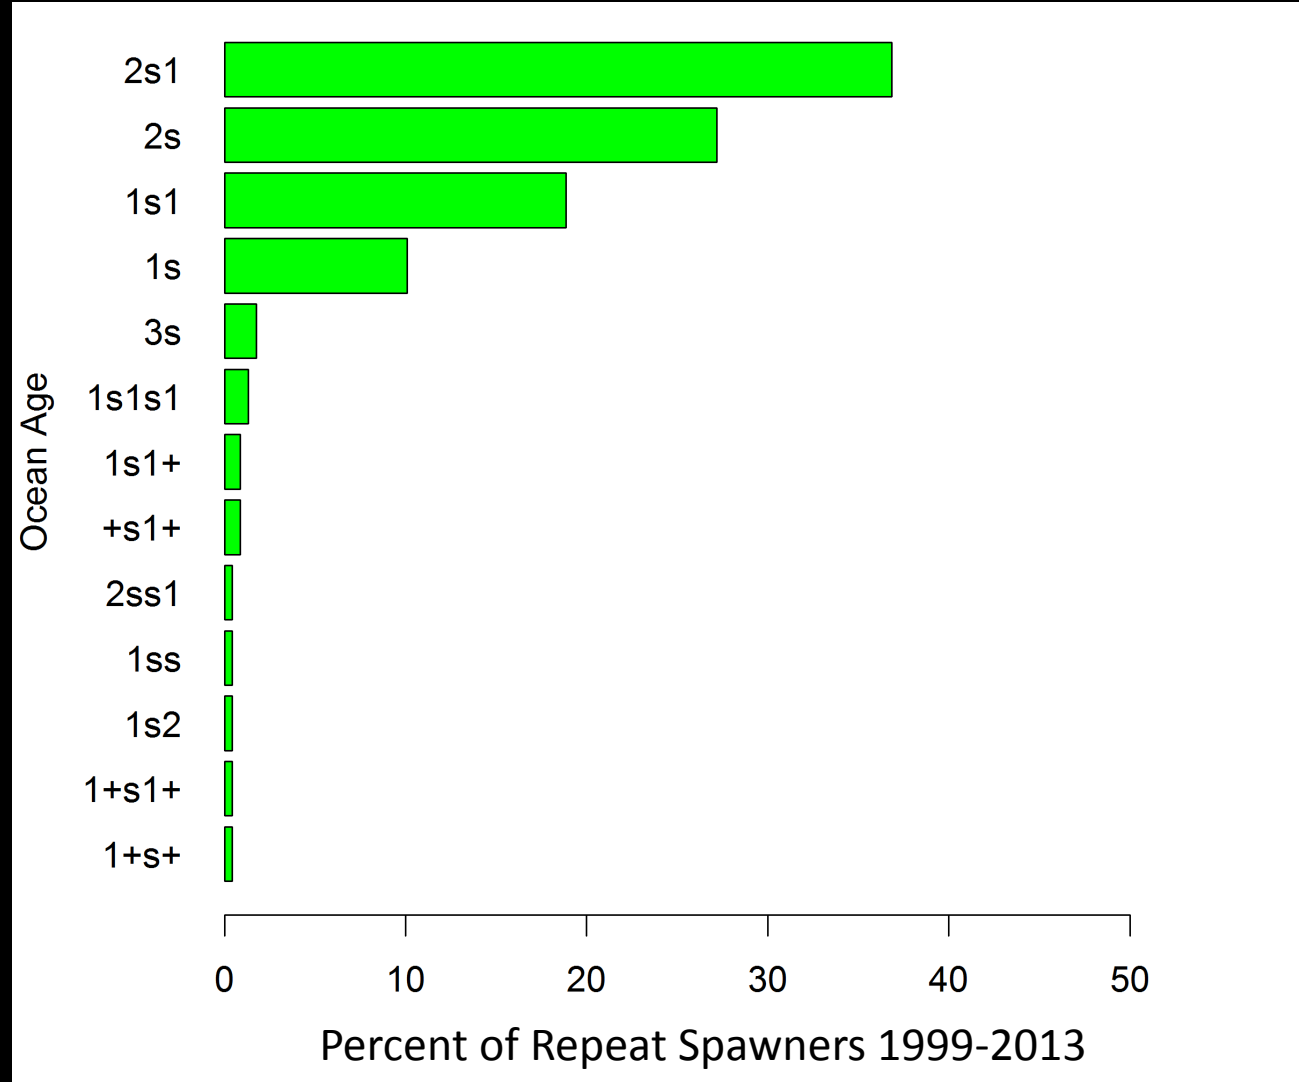

Results: Rates of Iteroparity

Repeat spawners varied from 1.2 % to 13.5% of the run by spawn year

Results: Rates of Iteroparity

- Skip repeat 2 salt summers most common
- Annual repeat 2 salt summers second most common
- One salts of same categories next

Talk Outline

- Background on steelhead iteroparity
- Wind River data collection methods
- Rates of iteroparity
- Factors influencing iteroparity

Analysis of iteroparity

- Factors affecting iteroparity
 - *H₀*: no difference in probability of an individual repeat spawning
- Differences between maiden and repeat spawners
 - *H₀*: no difference in repeat and maiden timing at BON
 - *H₀*: no difference in length between maiden and repeats

Factors affecting iteroparity

H₀: No difference in probability of a maiden spawner repeat spawning by:

- GLM models—binomial response, with logit link function
- All subsets up to 3 variables tested (no interactions)
- Model selection with AIC
- Also ran model with year subset to include SAR

Variable	Continuous or Factor
Sex	F
Length	C
Run type (winter or summer)	F
Years since smolting at spawn	F
Days before spawning (common date)	C
Spawn Year	F
Tag Month	F
Previous Spawn History	F
SAR during kelt year	C

Results: Factors affecting iteroparity

H₀: No difference in probability of a maiden spawner repeat spawning by:

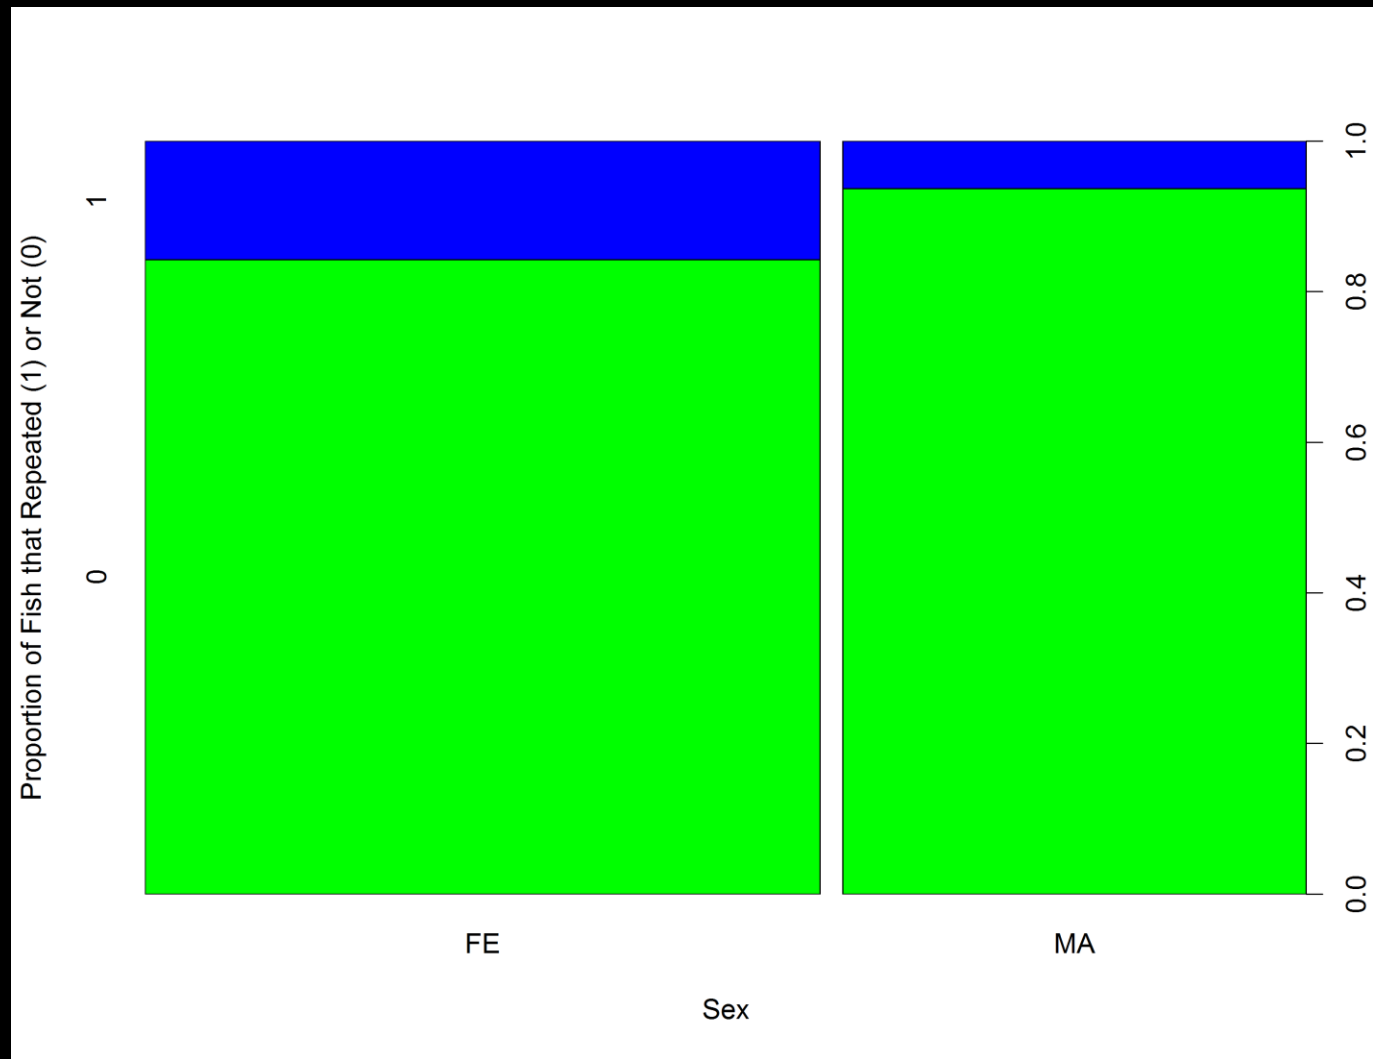

- Two models with delta AIC < 4)
 - One included Salt Age, one had Length, which were highly correlated
- Low explanatory power ($R^2 = 0.065$)

Variable	Continuous or Factor	Effect on repeat spawning
Sex	F	females more likely
Length	C	shorter fish more likely
Run type (winter or summer)	F	smaller fish more likely
Years since smolting at spawn	F	oldest fish less likely
Days before spawning (common date)	C	earlier arrivers more likely
Spawn Year	F	NS
Tag Month	F	NS
Previous Spawn History	F	NOT APPLICABLE
SAR during kelt year	C	NS

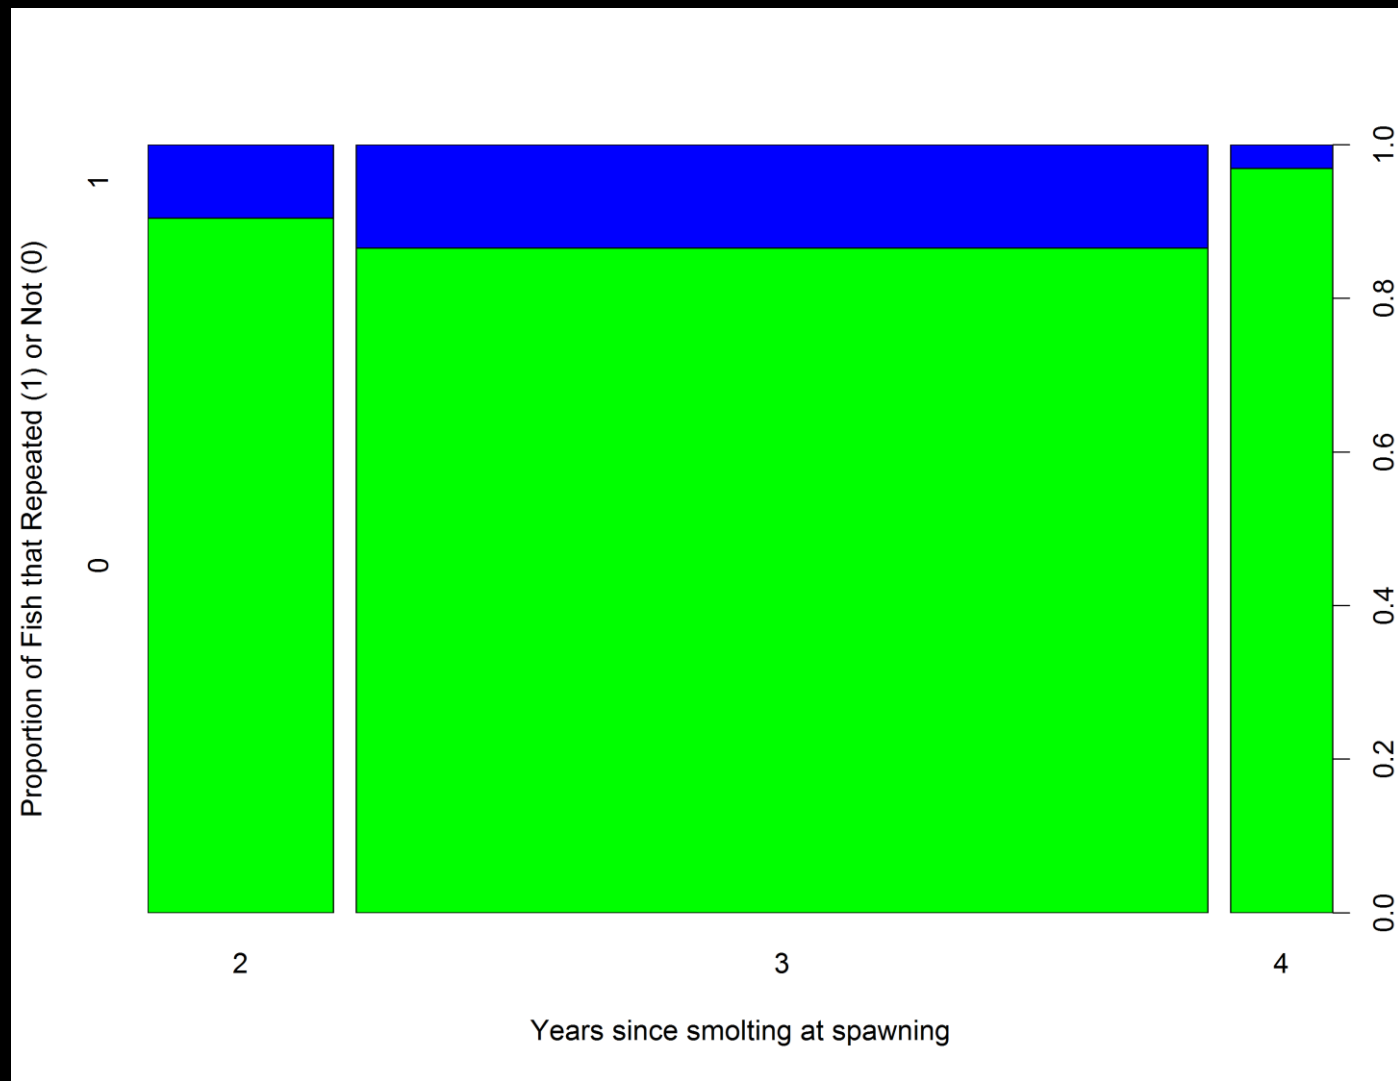

Results: Factors affecting iteroparity

Females more likely
to repeat spawn
(n = 1093)

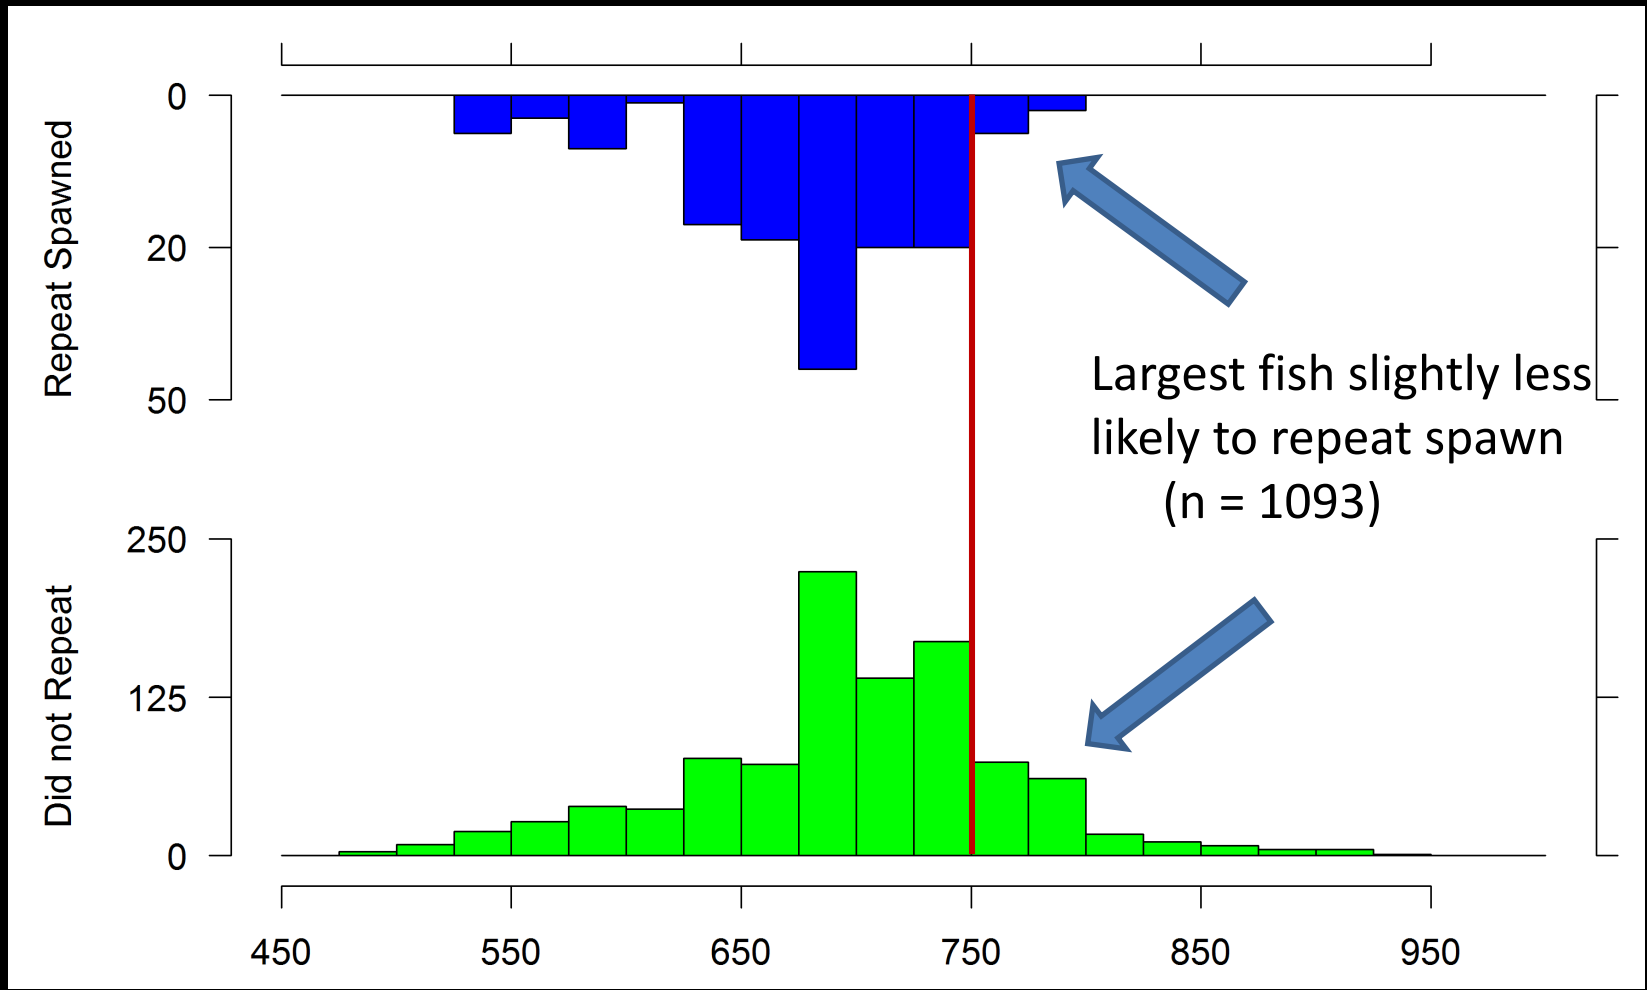

Results: Factors affecting iteroparity

Oldest fish less likely
to repeat spawn
(n = 1093)

Results: Factors affecting iteroparity

Results: Factors affecting iteroparity

- Few fish tagged in winter but none repeated to BON
- Declining proportion of summers repeat by month

Analysis of iteroparity

- *Ho*: no difference in probability of an individual repeat spawning
- *Ho*: no difference in repeat and maiden timing at BON

Results: Timing

- Repeats slightly later at BON
- Limited sample size
- Possible bias: maidens tagged as smolts, repeats tagged at Shipherd Falls

Analysis of iteroparity

- *Ho*: no difference in probability of an individual repeat spawning
- *Ho*: no difference in repeat and maiden timing at BON
- *Ho*: no difference in length between maiden and repeats

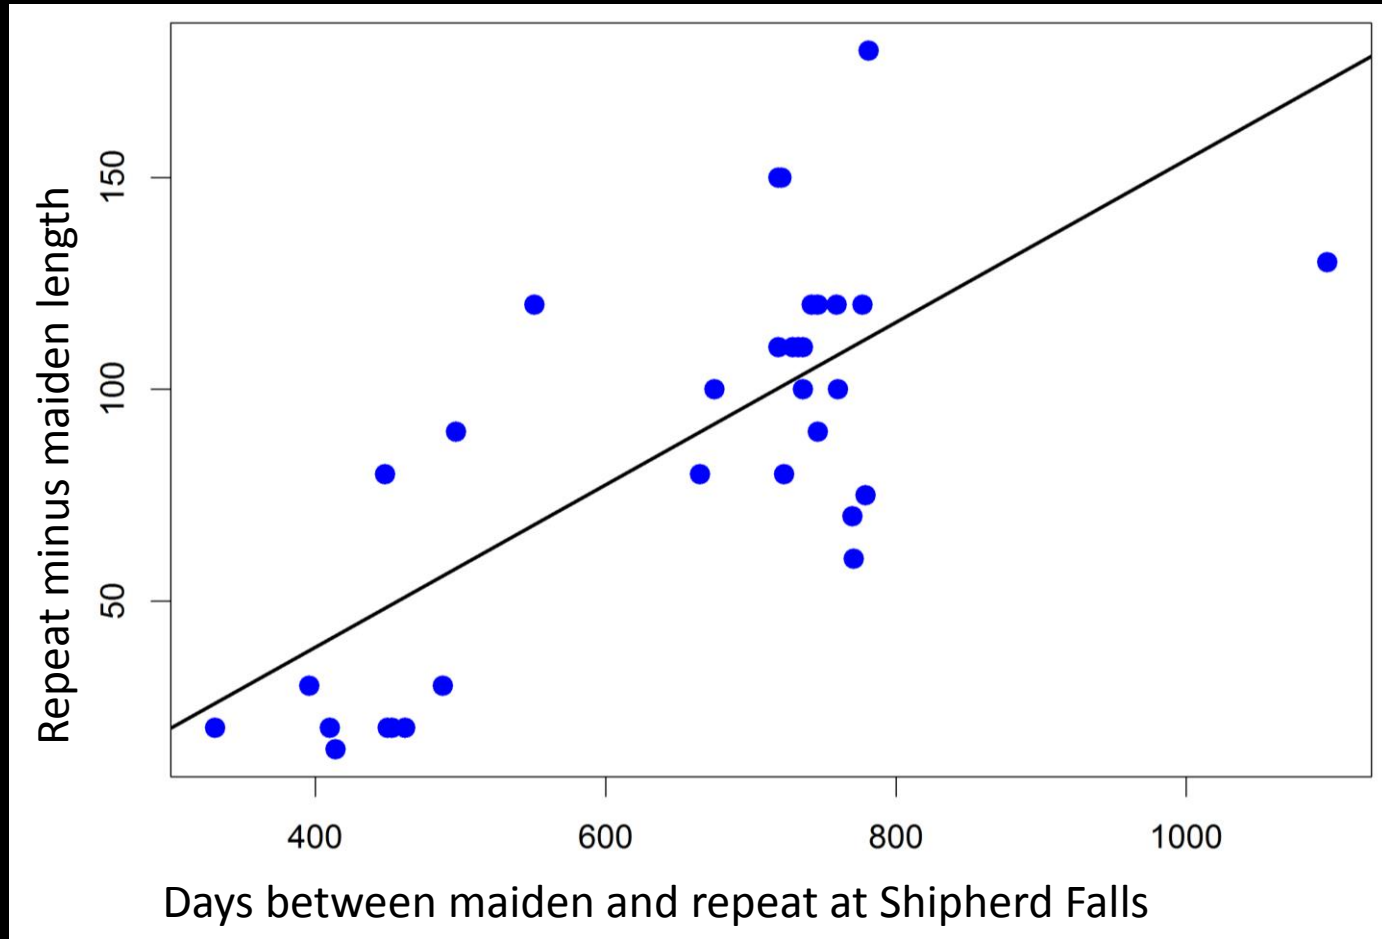

Results: Lengths

- Median length 48 mm larger for repeat spawners
- KS test $p \ll 0.001$

Results: Lengths

- Repeat spawners grew before repeating
- Length growth correlated with days between spawning

Talk Outline

- Background on steelhead iteroparity
- Wind River data collection methods
- Rates of iteroparity
- Factors influencing iteroparity
- Implications of iteroparity

Implications of Iteroparity

- Increase median abundance by 40 spawners and 6%
- Lower than median abundance years; 9%
- Reduce CV in abundance by 1.6%

Implications of Iteroparity

- Higher fecundity associated with greater length

Summary

- Iteroparity in Wind > than observed in Columbia; up to 13.5%
- Probability of repeat spawning for maidens correlated with:
 - Sex (females more likely)
 - Length (smaller more likely)
 - Timing (earlier more likely) !?
 - Age of maidens (oldest less likely)
- Repeat spawners larger, slightly later timed relative to maidens
- Growth of repeats increased with time
- Repeat spawners buffer declines in abundance
- Increasing iteroparity would likely benefit listed Columbia River populations

Extra Slides

Results: All Fish

H₀: No difference in probability of an individual repeat spawning by:

- One best model (delta AIC = 4.1)
- Low explanatory power ($R^2 = 0.06$)

Variable	Continuous or Factor	Effect on repeat spawning
Sex	F	females more likely
Length	C	shorter fish more likely
Run type (winter or summer)	F	smaller fish more likely
Years since smolting at spawn	F	NS
Days before spawning (common date)	C	earlier arrivers more likely
Spawn Year	F	NS
Tag Month	F	NS
Previous Spawn History	F	NS *but correlated with length
SAR during kelt year	C	NS
